Petras Avizonis Rocketdyne/BNA Presented to July 2, 1997

University of California

National Laboratory Lawrence Livermore

Our goal is to design, build and test a Yb:YAG laser at near-scale

Design goals of illuminator @ 1.03 μm:

2 kW, 8 kHz, 10-70 nsec, $M^2 = 1.2 - 2$

Costing strategy of campaign

CRADA \$\$ to cover development of gain module

Rocketdyne \$\$ to cover external optics; implementation of amplifier configuration

Diode power compatible with long-term reliability is 45 W/package => 100 packages = 4.5 kW

for 1 kW power operation this implies 22% conversion efficiency

> 1 kW power operation plausible for brief periods of time (60 W/package)

Yb:YAG gain medium - minimizes heat generation (8.6% for Yb:YAG vs. >24% for Nd:YAG)

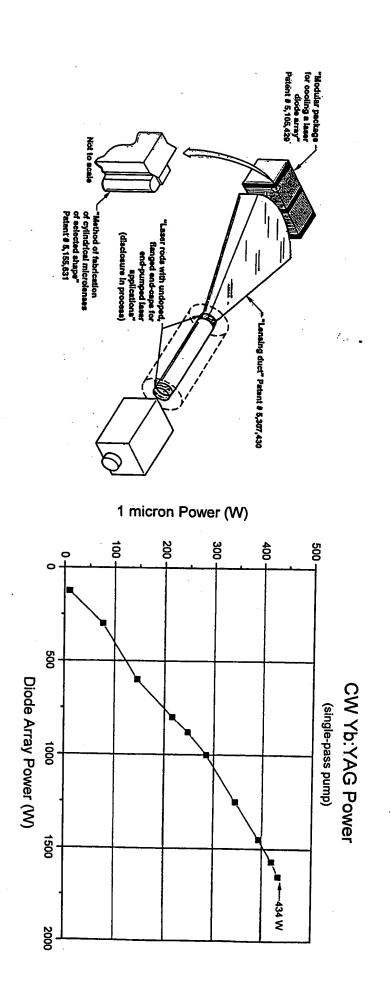

Diode pumping - efficiency, reliability, low heating, compactness, etc.

Zig-zag slab - cancels birefringence and themal focus, except for end and edge effects

8-pass amplifier layout with birefringence compensation - use Faraday rotator(s) to avert depolarization

Corrective optic - improve beam quality by fabricating phase corrective mirror (based on interferometric measurements)

at a 10 kHz PRF and a 27 nsec pulse duration Also, 220 W of average power Q-switched output has been generated

Proprietary

laser The slab design is scaled from our 434 W Yb:YAG rod

	400 W rod (demonstrated) (400 W rod kW slab (demonstrated) (in fabrication-FY97)	multi-kW slab (proposed)
Pump power	1.7 kW	4.5 - 6 kW	Wy 6
Aperture	2 mm ø (3.1 mm ²)	$2.5 \times 3.5 \text{ mm}$ (8.75 mm ²)	2.5 x 7.0 mm (17.5 mm ²)
Stress fracture	15%	24 - 32%	24%
Surface heat flux	24 W/cm ²	43 - 57 W/cm ²	43 W/cm ²
Output power	434 W	1.2 - 1.8 kW	2.5 kW

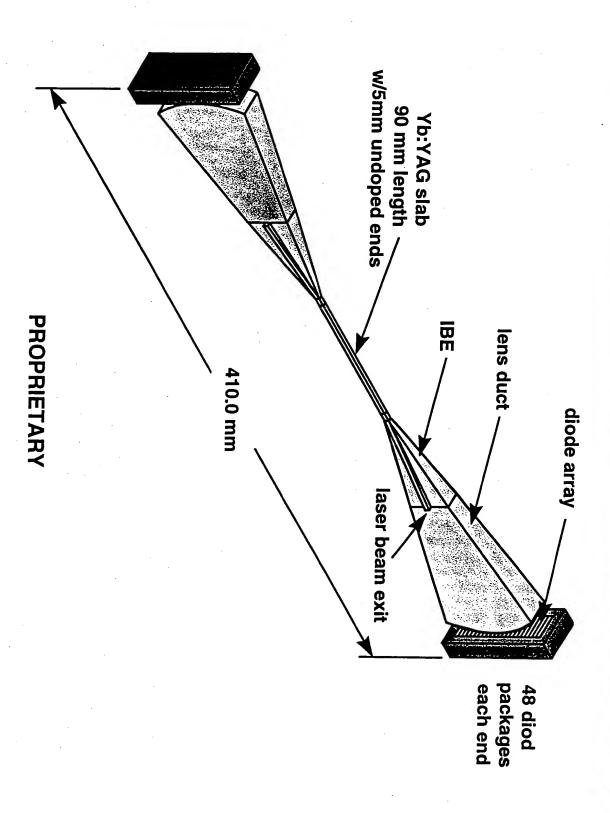

Our slab design gracefully scales to 2 - 4 kW by simultaneously increasing the height of the diode array (number of diode bars) and the height of the slab

Slab edge effects are minimized for higher power designs due to higher slab aspect ratio

PROPRIETARY

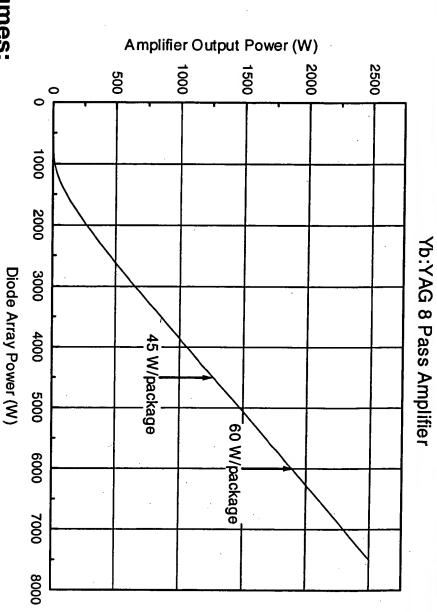

kW dual-end-pumped Yb:YAG gain module

Energetics modeling of 8 kHz amplifier

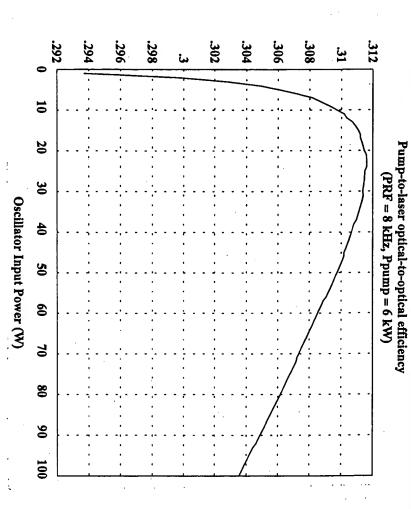

Assumes:

- 80% fill factor
- Losses of 5% per pass
- Diode array power of 6 kW leads to 1.8 kW of average ouput power Front end energy of 2.5 mJ (20 W average power at 8 kHz)

is needed to yield 236 mJ at the output Energetics modeling indicates that 2.5 mJ of input energy

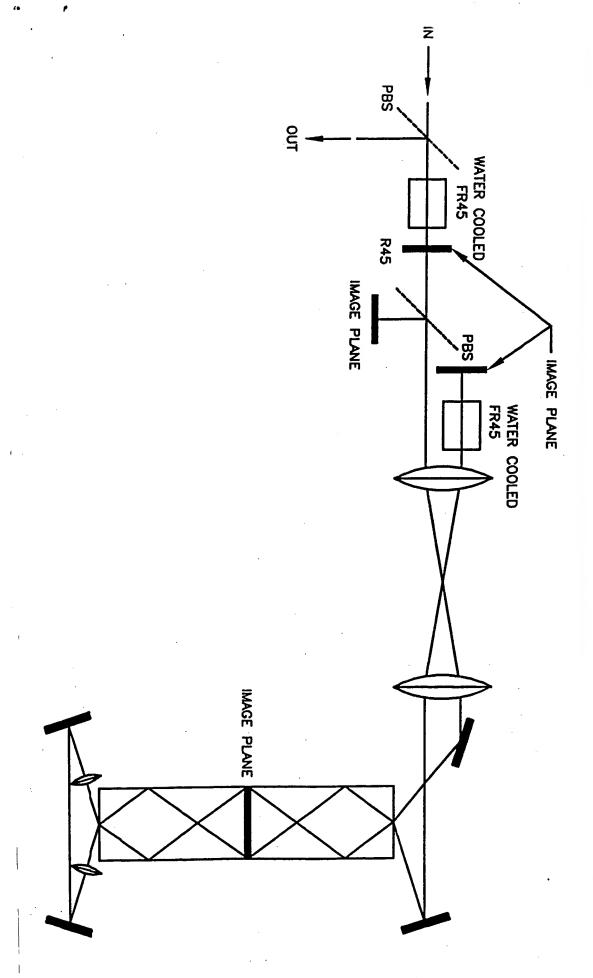

- Assumes:
- 80% fill factor
- Diode array power of 6 kW leading to 1.8 kW of average output power
- Losses of 5% /pass
- 32% of fracture limit @ 8 kHz

with compensation of residual thermally-induced Amplifier layout incorporates 8-passes through slab birefringence

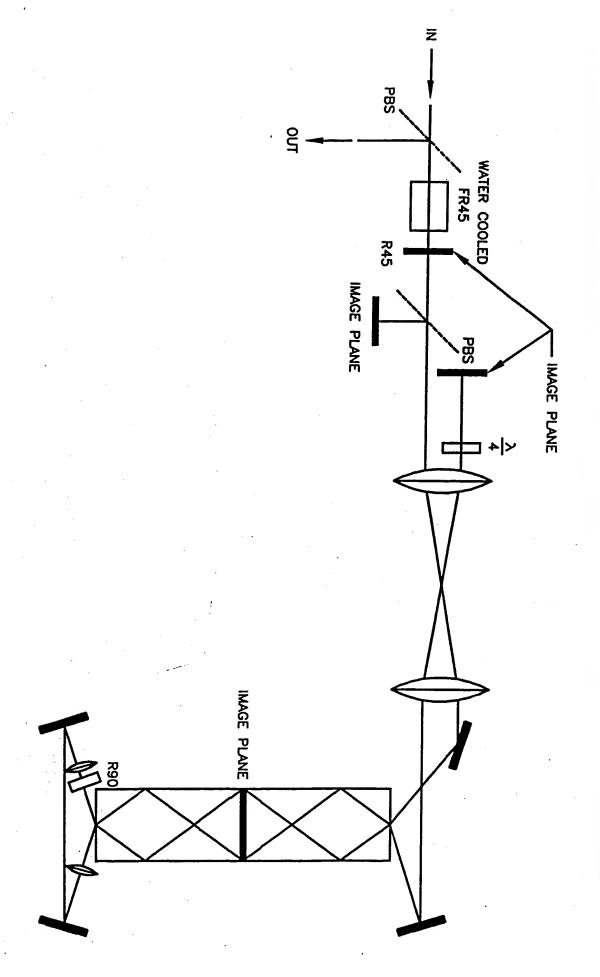

- Sed
- Two layouts have been identified with similar features:
- -compensation of residual thermally-induced birefringence
- -8 passes through slab
- -relay imaging of slab mid-plane
- -water-cooled high-power Faraday rotator in output beam
- static phase corrective optic to improve beam quality
- (phase distortion to be determined by interferometry at 1.064 μm)

Faraday rotator for birefringence compensation Conceptual layout of system using an intracavity 45°

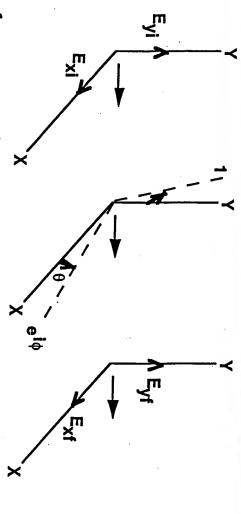

quartz rotator for birefringence compensation Conceptual layout of system using an intracavity 90°

acting as an arbitrary wave plate for any allowed ray path proposed approach relies on the laser gain medium Tl birefringence compensation t⊾thnique used in our

Jones matrix for a wave plate with retarding axis (phase delay ela) at an angle of θ w.r.t. x - axis

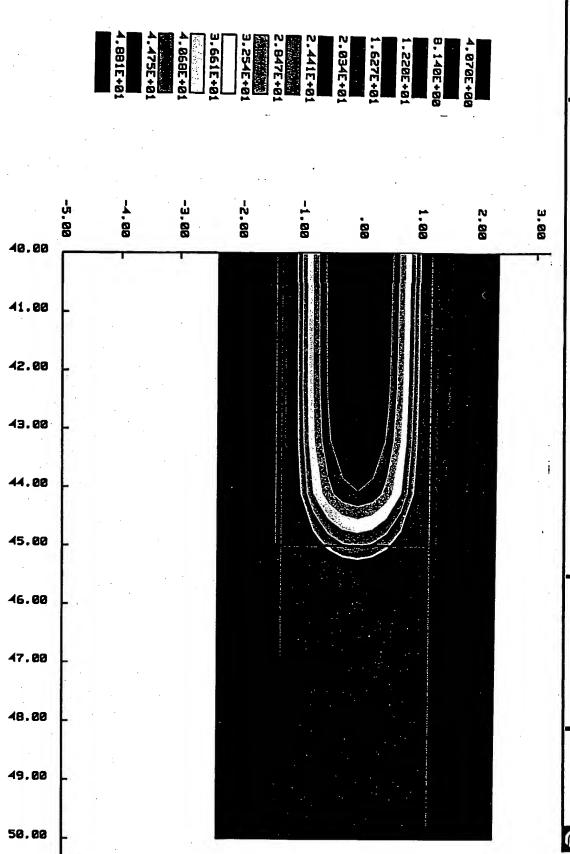

$$\begin{pmatrix} E_x \\ E_y \end{pmatrix}_f = \begin{pmatrix} \sin^2 \theta + e^{id} \cos^2 \theta & (e^{i\phi} - 1) \sin \theta \cos \theta \\ (e^{i\phi} - 1) \sin \theta \cos \theta & e^{i\phi} \sin + \cos^2 \theta \end{pmatrix} \begin{pmatrix} E_x \\ E_y \end{pmatrix}_i$$

is equivalent to a phase retardation and a 90° rotation Double passing the same waveplate with a 90° rotator between passes

$$\left(\sin^{2}\theta + e^{id} \operatorname{^{P}\cos^{2}\theta} \left(e^{i\phi} - 1\right)\sin\theta\cos\theta\right)\left(0 - 1\right)\left(\sin^{2}\theta + e^{id}\cos^{2}\theta \left(e^{i\phi} - 1\right)\sin\theta\cos\theta\right) = e^{i\phi}\left(0 - 1\right)\left(\left(e^{i\phi} - 1\right)\sin\theta\cos\theta\right) = e^{i\phi}\left(1 - 0\right)$$

compensation introduces simple lensing. In a slab things are more complicated For a uniformly loaded rod ϕ varies quadratically with radius and birefringence will need to be compensated with a static corrector.

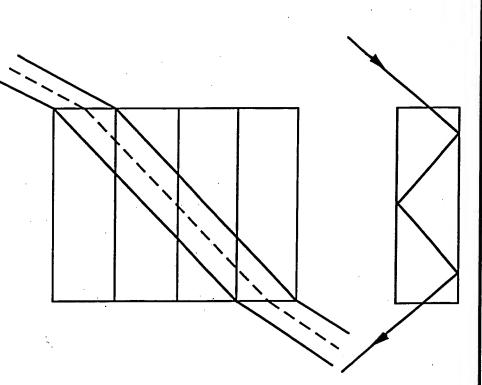

the temperature field near the slab undoped endcaps Phase distortion due to end effects can be estimated from

aperture due to imperfect temperature gradient Conceptual approach to OPD calculation across slab

3 bounce path

Method of images

refractive-index-field construction

of code are being developed to include $rac{dn}{d\sigma}$ as well Present modeling includes $\frac{dn}{dT}$ effects. Future versions

Proprietary

module design issues In the next three months we will benchmark key gain

Suppression of parasitic modes

- -design relies on roughened low-index coatings to disrupt trapped parasitic ray paths while reflecting pump light
- -test coupons have been ordered from Quality Thin Films (Tarpon Springs, FL)

Removal of waste heat, including energy deposited in hardware due to fluorescence

- -copper macrochannel chill bars are being fabricated
- Efficient pump light delivery to slab that enables laser radiation to be extracted through pump concentrator (lens duct)
- extractor)--ordered -solid optic fabricated from undoped YAG (intermediate beam
- -backup design based on hollow lens duct is being modeled

Proprietary

Parasitics suppression required with slab geometry

without trapping parasitic modes Problem: TIR pump in the slab

ground outer surface \sim 5 μ m thick coating (n=1.4 - 1.6) with

Parasitics

(no loss) if $\theta > \theta$ critical ray A undergoes TIR

ray may TIR at outer surface if not ground

if θ critical < 45° then ray B may also

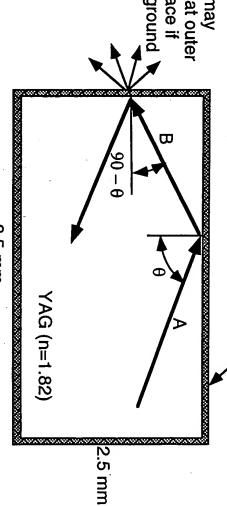

=> trapped ray with no loss!

apply ~ 5 μm thick coating (n=1.4 Solution:

1.6) with ground outer surface

need it just thick enough that to ground surface or Cu chill block evanescent wave doesn't leak through

conductivity) want it thin to minimize thermal impedance (probably low thermal

3.5 mm

YAG/air:

 θ critical = 33.3°

YAG/(n=1.6): $\theta_{critical} = 61.5^{\circ}$

YAG/(n=1.4): $\theta_{critical} = 50.3^{\circ}$

 θ critical = 38.7

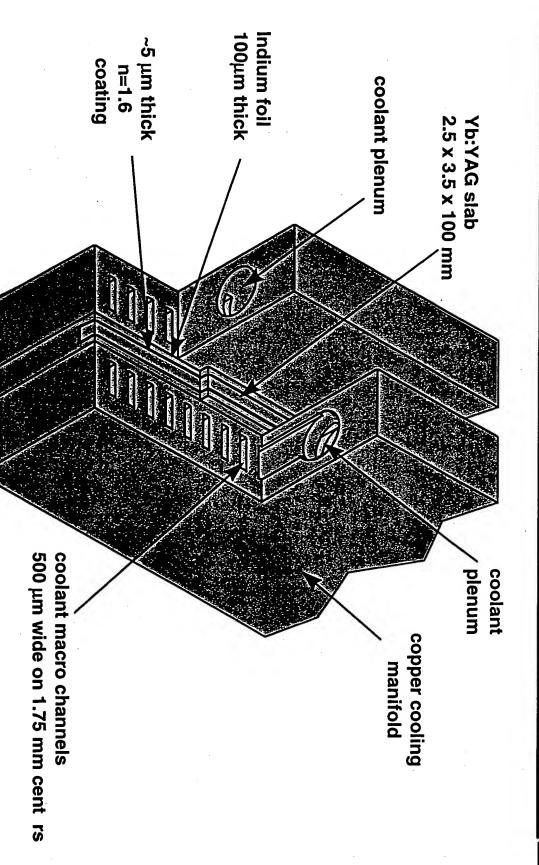

(n=1.6)/air: (ground outer surface required)

(n=1.4)/air: θ critical = 47.7°

procurements have arrived Testing of the gain module will begin as soon as all of the

All of the components to test the gain module as a power oscillator have been designed and ordered

Fabrication times for slab and beam extractors will be longer than those originally quoted by vendor

- -slabs to be completed week of 7/21
- -YAG beam extractors not expected until week of 8/11
- -hollow lens duct will be fabricated as back-up

Hardware is being machined, nearly completed

Test coupons with roughened low-index coatings have been ordered

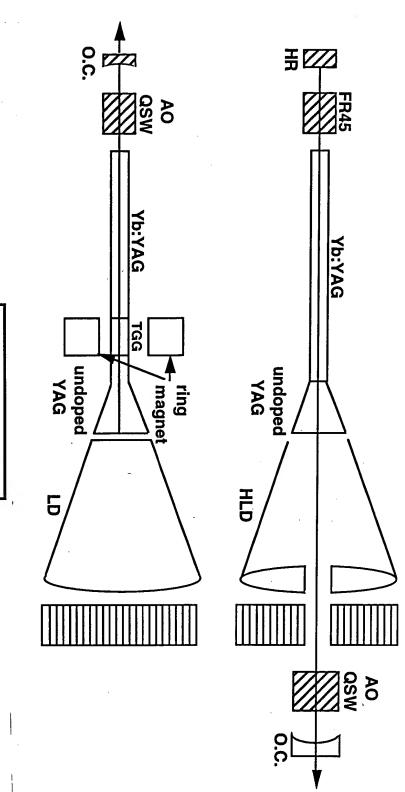

- -different film thicknesses: 3, 5, 7 and 9 μm SiO2
- -we will compare surface treatments, starting with bead-blasting

PRO, AIETARY

to 40W of average Q-switched power at 8 kHz will be A high beam quality front end capable of delivering up required

compensation and some development A rod laser is the simplest approach, but this will require birefringence

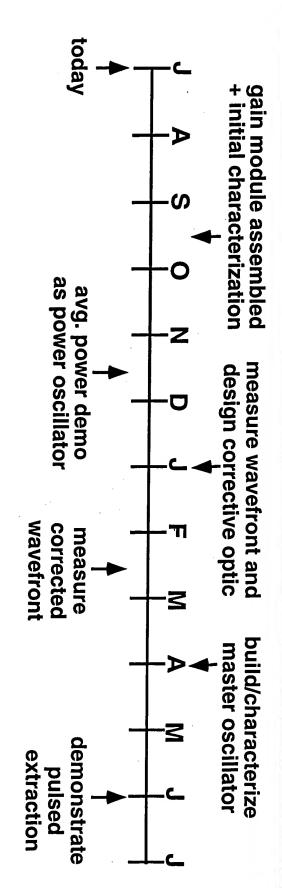

PROPRIETARY

The schedule contains several milestones and markers

Rocketdyne costs (\$400K total)

Optics and mounts (6 lenses, 5 mirrors, 2 Faraday rotators, 1 quartz rotator, 2 polarizers): \$50K including \$15 K contingency

Labor (9 months technician, 9 months scientific staff): \$250K

Oscillator (40 W, 5 mJ/pulse, TEM00): \$100K (25K head; 15K cooler, 5K power supply; 20K optics and coatings)

-could be reduced if existing module is available or low rep-rate osc.
